### CSC 580 Principles of Machine Learning

# 02 Limits of Learning

**Jason Pacheco** 

**Department of Computer Science** 

\*slides credit: built upon CSC 580 Fall 2021 lecture slides by Chicheng Zhang & Kwang-Sung Jun

### Motivation

• Machine learning is a general & useful framework...but it's not "magic"

• Understand when machine learning will and will not work

# Optimal classification with known D

#### Suppose

- Binary classification: 0-1 loss  $\ell(y, \hat{y}) = I(y \neq \hat{y})$
- Data Generating distribution *D* known for every (*x*, *y*)

#### **Generalization Error**

$$L_D(f) = E_{(x,y)\sim D}I(y \neq f(x)) = P_{(x,y)\sim D} (y \neq f(x))$$

#### Question

What is the f that minimizes,

$$L_D(f) = P_{(x,y) \sim D}(y \neq f(x))$$

### Simple case: discrete domain ${\mathcal X}$

Which classifier is better?

- $f_1(1) = -1, f_1(2) = -1, f_1(3) = -1 \implies L_D(f_1) = 0.1 + 0.3 + 0.05$
- $f_2(1) = -1, f_2(2) = +1, f_2(3) = -1 \implies L_D(f_2) = 0.1 + 0.2 + 0.05$

#### Is this the best classifier? Why?

- For any x, should choose y that has higher value of  $P_D(x, y)$
- $f^*(1) = -1, f^*(2) = +1, f^*(3) = -1$

### Bayes optimal classifier

**Theorem**  $f_{BO}$  achieves the smallest 0-1 error among all classifiers.

$$f_{BO}(x) = \arg \max_{y \in \mathcal{Y}} P_D(X = x, Y = y) = \arg \max_{y \in \mathcal{Y}} P_D(Y = y \mid X = x), \forall x \in \mathcal{X}$$

#### **Example** Iris dataset classification:

### Proof of theorem

Step 1 consider accuracy,

• 
$$A_D(f) = 1 - L_D(f) = P_D(Y = f(X)) = \sum_x P_D(X = x, Y = f(x))$$

• Suffices to show  $f_{BO}$  has the highest accuracy

Step 2 comparison,

$$A_D(f_{BO}) - A_D(f) = \sum_{x} P_D(X = x, Y = f_{BO}(x)) - P_D(X = x, Y = f(x)) \ge 0$$
$$f_{BO}(x) = \arg\max_{y \in \mathcal{Y}} P_D(X = x, Y = y)$$

#### Remarks

- Similar reasoning can be used to prove the theorem with continuous domain  $\mathcal{X}$  (sum -> integral)
- This just shows deterministic classifier, can be extended to show BO is 0-1 optimal for all classifiers

Bayes error rate: alternative form

$$L_{D}(f_{BO}) = P_{D}(Y \neq f_{BO}(X))$$
  
=  $\sum_{x} P_{D}(Y \neq f_{BO}(x) | X = x) P_{D}(X = x)$   
=  $\sum_{x} (1 - P_{D}(Y = f_{BO}(x) | X = x)) P_{D}(X =$   
=  $\sum_{x} (1 - \max_{y} P_{D}(Y = y | X = x)) P_{D}(X =$   
=  $E [1 - \max_{y} P_{D}(Y = y | X)]$ 

x)

x)

• Special case: binary classification

• 
$$L_D(f_{BO}) = \sum_x P_D(Y \neq f_{BO}(x), X = x)$$
  
=  $\sum_x \min(P_D(Y = +1, X = x), P_D(Y = -1, X = x))$ 

When is the Bayes error rate nonzero?

$$L_D(f_{BO}) = \sum_{x} \min(P_D(Y = +1, X = x), P_D(Y = -1, X = x))$$

- Limited feature representation
- Noise in the training data
  - Feature noise
  - Label noise e.g. typo transcribing reviews
  - Sensor failure
  - Typo in reviews for sentiment classification
- May not be a single "correct" answer
- Inductive bias of the model / learning algorithm

marker 1

### Inductive Bias

### Training

Test

How would you label the test examples?

# Overfitting vs Underfitting

High training error High test error

Low training error Low test error

Optimum

Low training error High test error

# {Over,Under}-fitting

What is the inductive bias of a shallow decision tree?

- Underfitting: Can learn something but didn't
- Overfitting: Pay too much attention to idiosyncrasies to training data, and do not generalize well
- A model that neither overfits nor underfits is expected to do best

# Unbiased model evaluation using test data

**Your Boss says**: You may run your recommendation system to on our website only if error <= 10%!

- How can we prove that this is satisfied?
- Idea: reserve some data as test data for evaluating predictors

• Law of large numbers  $\Rightarrow L_{\text{test}}(\hat{f}) \rightarrow L_D(\hat{f})$ 

# Law of large numbers (LLN)

- Suppose  $v_1, ..., v_n$  are independent random variables that are identically distributed, the sample average  $\bar{v} = \frac{1}{n} \sum_{i=1}^{n} v_i$  converges to  $E[v_1]$  as  $n \to \infty$
- Useful in e.g. election poll
- Foundations of statistics

# Never touch your test data!

- If  $\hat{f}$  depends on test examples,  $L_{\text{test}}(\hat{f})$  may no longer estimate  $L_D(\hat{f})$  accurately
- E.g. indirect dependence:
  - adaptive data analysis choose a new learning algorithm based on seeing that the previous algorithm produces a high-test-error model

# Case Study: MNIST Dataset

All publications use standard train/test split

What's the problem with this?

Hundreds of publications compare to each other

# Supervised learning setup

iid training data S has low generalization error

Generalization error:  $L_D(f) = E_{(x,y)\sim D} \ell(y, f(x))$ 

# Terminologies

- Model: the predictor  $\hat{f}$ 
  - Often from a model class  ${\mathcal F}$  ,
  - e.g.  $\mathcal{F} = \{ \text{decision trees} \}, \{ \text{linear classifiers} \}$

- Parameter: specifics of  $\hat{f}$ 
  - E.g. for decision tree  $\hat{f}$ : tree structure, questions in nodes, labels in leaves
  - For linear classifier: linear coefficients
- Hyperparameter: specifics of learning algorithm  ${\mathcal A}$ 
  - E.g. in DecisionTreeTrain, constrain to output tree of depth  $\leq h$
  - Tuning hyperparameters often results in {over, under}-fitting

# Hyperparameter tuning using validation set

- E.g. in decision tree training, how to choose tree depth  $h \in \{1, ..., H\}$ ?
- For each hyperparameter h ∈ {1, ..., H}:
  Train Tree<sub>h</sub> using DecisionTreeTrain by constraining the tree depth to be h
  Choose one from Tree<sub>1</sub>, ..., Tree<sub>H</sub>
- Idea 1: choose  $Tree_h$  that minimizes training error
- Idea 2: choose Tree<sub>h</sub> that minimizes test error
- Idea 3: further split training set to training set and validation set (development/hold-out set), (1) train Tree<sub>h</sub>'s using the (new) training set; (2) choose Tree<sub>h</sub> that minimizes validation error

# Hyperparameter tuning using validation set

• E.g. in decision tree training, how to choose tree depth  $h \in \{1, ..., H\}$ ?

• Law of large numbers => Validation error closely approximates test error & generalization error

### Model Selection / Assessment

#### Partition your data into Train-Validation-Test sets

- Ideally, Test set is kept in a "vault" and only peek at it once model is selected
- Training-Validation-Test splits work if you have enough data ("data rich")
- As a general rule 50% Training, 25% Validation, 25% Test (very loose rule)

Source: Hastie, Tibishrani, Freidman

# Overfitting vs Underfitting

Underfitting performs poorly on *both* training and validation...

... overfitting performs well on training but not on validation

# KNN Model Selection / Assessment

1. Train a set of models K=1,...,K<sup>max</sup> on training data:

 $\operatorname{model}_{K=1}(\mathcal{D}^{\operatorname{train}}), \ldots, \operatorname{model}_{K=K^{\max}}(\mathcal{D}^{\operatorname{train}})$ 

2. Evaluate model accuracy on validation data:

 $\operatorname{Error}(\operatorname{model}_{K=1}, \mathcal{D}^{\operatorname{val}}), \ldots, \operatorname{Error}(\operatorname{model}_{K=K^{\max}}, \mathcal{D}^{\operatorname{val}})$ 

3. Select model with lowest validation error:

 $K^* = \arg \min_K \operatorname{Error}(\operatorname{model}_K, \mathcal{D}^{\operatorname{val}})$ 

3. Evaluate model error on test:

What are some drawbacks of this approach?

 $\operatorname{Error}(\operatorname{model}_{K^*}, \mathcal{D}^{\operatorname{test}})$ 

### **Cross-Validation**

**N-fold Cross Validation** Partition training data into N "chunks" and for each run select one chunk to be validation data

For each run, fit to training data (N-1 chunks) and measure accuracy on validation set. Average model error across all runs.

**Drawback** Need a lot of training data to partition.

Source: Bishop, C. PRML

# Hyperparameter tuning: cross-validation

- Main idea: split the training / validation data in multiple ways
- For hyperparameter  $h \in \{1, ..., H\}$ 
  - For  $k \in \{1, \dots, K\}$ 
    - train  $\hat{f}_k^h$  with  $S \setminus \text{fold}_k$
    - measure error rate  $e_{h,k}$  of  $\hat{f}_k^h$  on fold<sub>k</sub>
  - Compute the average error of the above:  $\widehat{\operatorname{err}}^h = \frac{1}{K} \sum_{k=1}^{K} e_{h,k}$
- Choose  $\hat{h} = \arg\min_{h} \widehat{\operatorname{err}}^{h}$
- Train  $\hat{f}$  using S (all the training points) with hyperparameter  $\hat{h}$
- k = |S|: leave one out cross validation (LOOCV)
